PART B: APPLICATIONS OF MACHINE LEARNING SKILLS

Machine learning has become one of the most transformative technology which enables the companies to make use of the commercial benefits. Day by day we could see the development and improvement in the machines that are being used in industries. The current co-operate world is requiring and depending on the technology for the all the jobs to be completed. Machine learning is a process that abstracts the interaction of human and computer. As we investigate on the commercial benefits to companies of machine learning there is more and more that we can point out.

Machine learning is process where the algorithms and data meets up the requirements of a targeted feature. Machine learning techniques use the advanced algorithms and large datasets which is for a targeted audience. Machine learning techniques also uses some the techniques such as unparalleled insights, automation and the optimization possibilities.

As per my investigation, there are two commercial benefits for the companies. The first one to be mentioned is that the "Personalized Marketing Campaigns". This focuses on the customers / which is also known as the targeted audience. In this technique the company can easily segment their audience and predict the customer behavior as where the machine learning algorithms can identify the pattern of the particular data. Therefore it is the easiest way to the companies to deliver the targeted advertisements, offers and recommendations which as a result the engagement of the customers will increase.

As an example for this I select the case study of Netflix, this is because Netflix is a platform which uses the machine learning techniques in their contents and advertising which attract their targeted audience. This makes the user to watch the TV shows, series and movies which are attractively shown in the Netflix social platform. This machine learning techniques contributes more of the outcome to platforms like this where the companies benefit.

The second mentioned benefit is that the machine learning technique allows the companies to maintain their data systematically and organized. Which means in order to collect the censored data the companies use the highest range of algorithms which is the quicker method of storing data of a targeted audience. This machine learning technique prevents in maintaining the data with secured algorithm.

While machine learning offers plenty of benefits to the companies, there are also risks associated with it. It requires a more of challenges. Whereas there can be a very low quality of the data responses and also incomplete data can provide a response of inaccurate predictions. So this leads to a regular audits and monitoring of data that is stored in order to make the accuracy of the data model. This will lead to a must in focusing on the data integrity, transparency and diversity for the companies.

The second risk associated is that the companies will have to have concerns on the ethical and privacy concerns while depending on the machine learning techniques. Because collection of data is very sensitive where the companies have to consider in handling the data in a correct way. Whereas mishandling of data can result a major shut done of the company.

As my conclusion I would like to mention my thoughts here, machine learning techniques and the uses of the algorithm allows the companies in benefits of development and growth. But there should be concerns in considering the drawbacks and the risks that area associated with machine learning. Therefore depending on the machine learning the companies will have to aware of both the positive and negative traits that are associated in facing them.
